A Quasi-experimental Study on Effectiveness of Cabbage Leaves Application for Breast Engorgement in Postnatal Mothers at Selected Hospitals, Amritsar, Punjab, India

¹Rajbir Kaur, ²Parvesh Saini

ABSTRACT

Introduction: Breast engorgement occurs in 72 to 85% of postnatal mothers. One home remedy, i.e., cabbage leaves application, is very effective for engorgement. The objective of the study was to assess the effectiveness of cabbage leaves application on breast engorgement among postnatal mothers.

Materials and methods: The study was conducted in tertiary care medical institute and one private hospital in Amritsar. Totally, 63 (33 in study and 30 in control group) postnatal mothers with engorgement of breast were selected by purposive sampling technique and quasi-experimental design was adopted. Storr breast engorgement scale was used to assess the breast engorgement. The chilled cabbage leaves were applied on engorged breast twice a day for 3 subsequent days. The obtained data were analyzed by using descriptive and inferential statistics like frequency, percentage mean, standard deviation, unpaired t-test, and Chi-squared test.

Results: The study result showed that there was reduction in breast engorgement level after the intervention and also showed statistically highly significant difference in between the groups.

Conclusion: There was a significant reduction in severity of breast engorgement among postnatal mothers after application of chilled cabbage leaves. Thus, it was proved to be an effective intervention for severity of breast engorgement. Therefore, this intervention should be promoted as an institutional policy and implemented as a routine care for all postnatal mothers having breast engorgement for reducing severity of breast engorgement.

Keywords: Breast engorgement, Cabbage leaves application, Home remedy, Postnatal mothers.

INTRODUCTION

The birth of a baby is an important event in any family.¹ It is, therefore, important that for a mother to have a healthy baby, she gives her baby the best nutrition. Breast milk is the best food for babies as breastfed babies are generally healthier than formula-fed ones.² The mammary gland is a milk-producing gland, which is composed largely of fat. It is a complex network of branching ducts and sac-like structures called lobules, which produce milk. Breast tissue fluid drains through the lymphatic into the lymph nodes located in the axilla and behind the sternum.³ Immediately after birth, the mother produces colostrum, a yellow sticky fluid secreted by breast that provides nutrition and protects against infection.

Breast engorgement usually happens when the breasts switch off from colostrum to mature milk.⁴ As milk production increases, overdistention of the alveoli causes the milk-secreting cells to become flattened and occlude the capillary blood circulation surrounding the alveolar cells. Congestion contributes to edema and obstructs lymphatic drainage of the breasts, stagnating the system that rids the breasts of toxins and bacteria, and leading to mastitis. In very severe cases, there can be numbness or tingling of the hands from pressure on the nerves. In addition, a protein called the feedback inhibitor of lactation accumulates in the mammary gland during milk stasis. It acts as a major trigger of apoptosis, that causes involution of the milk-secreting gland, collapse of the alveolar structures, and the cessation of milk production.⁵ Breast engorgement and infection are responsible for puerperal pyrexia.⁶ Engorgement may lead to mastitis.^{7,8} Subareolar tissue resistance also increases during engorgement and results in latching difficulty.⁹ According to the Academy of Breastfeeding Medicine Protocol Committee and Berens,¹⁰ breast engorgement is defined as “the swelling and distension of the breasts, usually in the early days of initiation of lactation, caused by vascular dilatation as well as the arrival of the early milk.”

Cabbage leaves have been used for centuries as a folk remedy for a wide variety of ailments and received much renewed interest from lactation professionals over the past 10 years. It contains a natural mixture of ingredients that helps to decrease tissue congestion by dilating local

capillaries in mild, moderate, and severe discomfort.¹¹ Ayers¹² stated that this natural mixture of ingredients from Mother Nature's Kitchen helps decrease tissue congestion by dilating (opening) local capillaries (small blood vessels), which improves the blood flow in and out of the area, allowing the body to re-absorb the fluid trapped in the breasts. Cabbage may also have a type of drawing or wicking action that helps move trapped fluid. Elizabeth¹³ stated that cabbage leaf contains singrin rapine, magnesium, oxalate, and many other nutrients. It is also believed to have antibiotic as well as anti-irritant properties.

In addition, the review of literature and investigator's own experience, while being posted in clinical settings, motivated the investigator to use cold cabbage leaves for relieving breast engorgement. Moreover, it is a home remedy and mothers who are not able to get treatment from hospitals during puerperal period can derive benefits from this remedy.

Hence, this study is aimed to assess the effectiveness of chilled cabbage leaves application on breast engorgement among postnatal mothers admitted in the postnatal ward at selected hospitals, Amritsar, Punjab, India.

MATERIALS AND METHODS

A quasi-experimental study was conducted to assess the effectiveness of chilled cabbage leaves on engorgement of breast. The present study was conducted at selected hospitals in Amritsar, Punjab from December 15, 2012 to January 15, 2013. A total of 63 postnatal mothers having complaints of engorgement of breast were selected for the study. The purposive sampling technique was used to collect the data. The tool used for the study was demographic variables and Storr breast engorgement scale to collect the data. The technique was explained to the subjects and consent was also obtained. Demographic variables and breast engorgement level were assessed for both experimental and control groups.

Experimental group (33) mothers received chilled cabbage leaves compresses for relieving engorgement. During the study period, two subjects had discontinued the intervention due to discharge on request from the hospital and one subject suffered from reaction (redness) from cabbage leaves. Hence, the dropout rate of the study was 1% (3). Cabbage leaves were refrigerated for approximately 20 to 30 minutes. The temperature for chilled cabbage leaves was 18°C as assessed by a lotion thermometer and placed on the engorged breast. Bra was put on the top of the leaves to keep them in place. The cold cabbage leaves were applied twice a day for 3 subsequent days. It was done six times on each subject. The duration of each intervention was 30 minutes. Intervention was given by principal investigator herself. Postintervention scores of

breast engorgement were assessed with the same scale at the end of the 3rd day. Conceptual framework adopted for the study was modified Roy's adoption model. The data obtained were processed in MS Excel sheet. The statistical analysis was performed using the software STRATA.

Inclusion Criteria

- Postnatal mothers with breast engorgement
- Willing to participate in the study

Exclusion Criteria

- Mothers with allergy to sulfa drugs and cabbage
- Mothers with soft breast; mothers receiving lactation suppressant
- Mothers with infection in the breast, breast abscess, mastitis, broken skin of breast, and bleeding or cracked nipples

Data Collection Tools

- *Part I:* Demographic data: it contains the age, education, family income per month, habitat, gravida, type of delivery, day of delivery, type of feeding, site of breast engorgement, and condition of nipple.
- *Part II:* Storr scale for assessment of engorgement.

0–Normal and no pain

1–Breast beginning to feel full and mild pain

2–Breast heavy, slightly warm, and moderate pain

3–Breast warm and heavy and severe pain

4–Breast very hard and worst pain

RESULTS

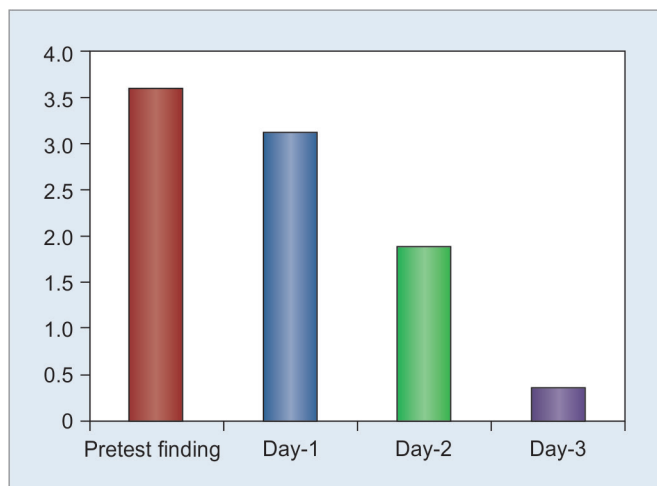

The obtained data were analyzed by using descriptive and inferential statistics. The two groups were found homogeneous with regard to all demographic and obstetric variables as analyzed by chi-squared test.

Table 1 and Graph 1 show that the highest mean score (3.63 ± 0.49) was obtained for pretest, whereas the lowest

Table 1: Breast engorgement score of experimental group before and after cabbage leaves application

<i>n</i> = 30	Mean	SD	Mean %	Paired	
				<i>t</i> -test	<i>p</i> -value
Pretest finding	3.63	0.49	90.83	1.034	0.305 NS
Day 1	3.13	0.78	78.33	5.39	<0.001**
Day 2	1.90	0.76	47.50	18.24	<0.001**
Day 3	0.37	0.61	9.17	30.67	<0.001**

**Highly significant at the level of <0.001; NS: Nonsignificant; SD: Standard deviation; Range: Minimum score 0; Maximum score 5

Graph 1: Breast engorgement score of experimental group before and after cabbage leaves application

mean score was (0.37 ± 0.61) . Hence, the differences in breast engorgement among postnatal mothers were highly significant in experimental group.

Table 2 shows that paired t-test indicates significant differences in breast engorgement among postnatal mothers that were observed only during the third day when compared with days 1 and 2.

In Table 3, the analysis shows that the significant difference in the mean breast engorgement score was observed only on day 3 in the control group, but the significant difference in the mean breast engorgement score was observed from day 1 in the experimental group among postnatal mothers after cabbage leaves application. Also, the highly significant difference was observed on days 2 and 3.

The paired t-test value was significant at the level of $p < 0.001$. This shows that the application of cabbage leaves on engorged breast was very effective. There was no statistical significant association between posttest breast engorgement scores with demographic variables.

DISCUSSION

The majority of the postnatal mothers were primiparous [21 (70%)] and 9 (30%) were multipara. Supporting these findings is a study conducted by Ruba¹⁴ that found that

Table 2: Breast engorgement score of control group before and after cabbage leaves application

No. of days for application (n = 30)	Mean	SD	Mean %	Paired	
				t-test	p-value
Pretest finding	3.50	0.51	87.50	1.034	0.305 NS
Day 1	3.47	0.51	86.67	1.00	0.326 NS
Day 2	3.53	0.63	88.33	-0.24	0.813 NS
Day 3	2.83	0.43	70.83	4.33	<0.000*

*Significant at the level of <0.05 ; NS: Nonsignificant; SD: Standard deviation

primigravida mothers were more prone to develop breast engorgement than multipara substantially.

The findings of pretreatment scores by using breast engorgement scale were found to be moderately painful in 10 (30%) and severely painful in 20 (70%) postnatal women. One study conducted by Joy and Kharde¹⁵ supported these findings where 1 subject (0.33%) complained of slight pain, 9 (30%) moderate, and 20 (66.67) complained of severe pain.

The findings of Roberts¹⁶ and Roberts et al¹⁷ also support this study because they reported that chilled cabbage leaves and cold gel packs were equally effective in reducing breast engorgement and pain in postpartum mothers.

This study was also supported by the finding of Ruba,¹⁴ who conducted a study to assess the effectiveness of cabbage leaves application on breast engorgement among postnatal mothers and found that application of cabbage leaves to relieve breast engorgement is very effective.

A study was conducted in Australia by Roberts et al¹⁸ to compare the effectiveness of chilled and room temperature green cabbage leaves in reducing discomfort due to breast engorgement among postnatal mothers. Mothers reported less pain with both the conditions, and the majority of the mothers preferred cold cabbage leaves.

Arora et al¹⁹ also compared the efficacy of cold cabbage leaves and hot and cold applications in the treatment of breast engorgement. They found that the cold cabbage leaves and hot and cold applications were both effective in decreasing breast engorgement.

Table 3: Comparison of pre- and postbreast engorgement test scores in experimental and control group

Day (n = 30 + 30 = 60)	Control group		Experimental group		t-value	p-value
	Mean	SD	Mean	SD		
Baseline	3.50	0.51	3.63	0.49	-1.03	0.305 NS
Day 1	3.47	0.51	2.90	0.66	3.72	<0.001*
Day 2	3.53	0.63	1.57	0.57	12.71	<0.001*
Day 3	2.83	0.75	0.43	0.50	14.59	<0.001*
F	9.14		192.78			
p	<0.001		<0.001			

*Significant at the level of <0.05 ; NS: Nonsignificant; SD: Standard deviation

Snowden et al,²⁰ who reviewed research studies to determine the effects of several interventions to relieve symptoms of breast engorgement among breastfeeding women, found that cabbage leaves were effective in the treatment of this painful condition. The results of the current study also showed that significant improvements in breast engorgement were observed postintervention ($p < 0.001$).

CONCLUSION

The study finding revealed that there was significant reduction of breast engorgement with chilled cabbage leaves application among postnatal mothers. Thus, it also proved that chilled cabbage leaves application can be effective in preventing further breast complications. It is a home remedy and a cost-effective method. Therefore, this intervention may be implemented as a routine care for all postnatal mothers having breast engorgement for reducing severity of breast engorgement.

ACKNOWLEDGMENTS

The authors are grateful to the postnatal women who participated in this study. The authors are also thankful to the statistician for performing the statistical analyses for this study.
